

from the coal storage area likely overstate actual emission rates. Even so, predicted concentrations would be less than $80 \mu\text{g}/\text{m}^3$ on all but one day per year. Ninety-nine percent (99%) of the time (i.e., 361 of 365 days per year), the maximum predicted contribution to ambient SPM levels due to fugitive coal dust would be less than $27 \mu\text{g}/\text{m}^3$. Furthermore, the predicted SPM concentrations due to fugitive dust from coal and ash storage of $0.5 \mu\text{g}/\text{m}^3$ and $0.3 \mu\text{g}/\text{m}^3$ respectively are negligible at the nearest residential areas west of the plant, and less than $0.2 \mu\text{g}/\text{m}^3$ at the nearest residence east of the plant. Therefore, fugitive dust emissions from the Brandon G.S. alone would not be sufficient to account for the high PM₁₀ (and by extension, SPM) concentrations that have been measured in Brandon.

6.5 Trace Contaminants

6.5.1 Mercury

As part of the Canada-wide Standard (CWS) proposed by the Canadian Council of Ministers of the Environment, Manitoba's mercury stack emissions from existing coal-fired electric power generation (EPG) plants are capped, commencing in the year 2010, at 20 kg/year. At this emission rate, the contribution of mercury emissions from the Brandon G.S. to total mercury deposition in the area surrounding the plant represents approximately 2-4% of the total mercury deposition including all global sources.

6.5.2 Other Trace Elements and Compounds

For the remaining trace contaminants in the exhaust emissions (i.e., VOCs, as well as trace organics and inorganics), only HCl, HF, formaldehyde, arsenic, cadmium, copper, lead, nickel, and zinc have established ambient air quality guidelines in Manitoba. The maximum predicted 24-hour average HF concentration is 1.5% of the guideline level. All other constituents are less than 0.1% of the Manitoba guideline values. Comparisons of maximum predicted concentrations for constituents with available air quality criteria from other jurisdictions indicate that all impacts are less than or equal to 0.6% of criteria levels, with the exception of the 1-hour average HF concentration at 3.7% of the Alberta objective level. The potential health impacts of these emissions are addressed in a separate document.

6.6 Greenhouse Gases

At 100% of capacity, the total potential greenhouse gas (GHG) emissions from Unit #5 is estimated at 1.04 megatonnes/year (Mt/yr). For the year 2000, the total emission of GHGs in Manitoba was estimated at 18.2 Mt/yr of CO₂-equivalent (Manitoba Environment 1998). Thus, the maximum potential GHG emissions from the Brandon G.S. are estimated at 5.7% of

Manitoba's total GHG emissions, but on average the station will produce fewer emissions than this. Total GHG emissions in Manitoba represent approximately 3% of Canada's total GHG emissions, and Canada contributes approximately 2% of the world's GHG emissions.

6.7 COOLING TOWER EMISSIONS

From the modelling that was undertaken it was determined that the potential impact from the cooling tower, it was concluded that the water vapour and dissolved salt emissions have a minimal impact on adjacent areas. Fogging or icing were predicted to occur off-site on approximately 1 hour per year and thus there is only minimal impact on the nearby roads. Assuming that the plant operates 100% of the time, a visible plume from the cooling tower of 500 m in length is predicted to occur up to 175 hours per year, while a plume up to 2 km in length may be visible for up to 88 hours per year. The amount of water and salt that may be deposited from the plume is negligible.

Datum-region

The Datum-Region for the coordinates is identified by a character string. Many mapping products currently available use the model of the Earth known as the World Geodetic System 1984 (WGS-84). Other local models may be in use, and their selection in CALMET will make its output consistent with local mapping products. The list of Datum-Regions with official transformation parameters is provided by the National Imagery and Mapping Agency (NIMA).

Note: MBCON > 0 requires that the last species modeled be 'BCON'. Mass is placed in species BCON when generating boundary condition puffs so that clean air entering the modeling domain can be simulated in the same way as polluted air. Specify zero emission of species BCON for all regular sources.

Analyses of fogging and icing impacts due to emissions from arrays of mechanically-forced cooling towers can be performed using CALPUFF in conjunction with a cooling tower emissions processor (CTEMISS) and its associated postprocessors. Hourly emissions of water vapor and temperature from each cooling tower cell are computed for the current cell configuration and ambient conditions by CTEMIS. CALPUFF models the dispersion of these emissions and provides cloud information in a specialized format for further analysis. Output to FOG.DAT is provided in either 'plume mode' or 'receptor mode' format.

118.7 E Longitude = 118.7E

Datum-region

The Datum-Region for the coordinates is identified by a character string. Many mapping products currently available use the model of the Earth known as the World Geodetic System 1984 (WGS-G). Other local models may be in use, and their selection in CALMET will make its output consistent with local mapping products. The list of Datum-Regions with official transformation parameters is provided by the National Imagery and Mapping Agency (NIMA).

For SINGLE SPECIES, the mean and standard deviation are used to compute a deposition velocity for NINT (see group 9) size-ranges, and these are then averaged to obtain a mean deposition velocity.

For GROUPED SPECIES, the size distribution should be explicitly specified (by the 'species' in the group), and the standard deviation for each should be entered as 0. The model will then use the deposition velocity for the stated mean diameter.
