INTRODUCTION

In 1996 the Manitoba Geological Services Branch (now the Manitoba Geological Survey) embarked upon a five-year program of helicopter- and fixed wing-assisted multimedia geochemical and mineralogical sampling. The program, called Operation Superior, was designed to assist in the definition of exploration targets and the assessment of mineral resource potential in the greenstone belts of the northern Superior Province. Preliminary results for the areas surveyed in 1996, 1997, 1998 and 1999 were released in Fedikow and Nielsen (1997) and Fedikow et al. (1997a, b, 1998, 1999, 2000).

A unique opportunity to assess the diamond potential in the northern Superior Province of Manitoba was made possible with the cooperation of DeBeers Canada Exploration Inc. Eleven-litre pails of till collected at each sampling site were concentrated, mineralogically picked and microprobed by DeBeers laboratories to provide mineral chemistry for classification purposes. Sample locations were withheld from DeBeers until release of the open file report to ensure security and equal opportunity for follow-up by all interested parties in the exploration community. This approach permitted diamond potential to be assessed throughout the 1996–2000 Operation Superior survey areas that under normal circumstances would have been too costly for the Manitoba Geological Survey to undertake.

This open file departs from the previous Operation Superior releases in that the results of kimberlite indicator mineral (KIM) surveys are normally reported along with rock, a- and b-horizon soil, till and vegetation geochemical data. This report presents the results of KIM survey data generated in year five (2000) of Operation Superior (Fig. 1). It is being released separately in advance of the full multimedia database, in response to the current record levels of diamond exploration activity in east-central Manitoba. At the time of writing, 21 companies had taken out a total of 68 permits covering 30 178 km². A report summarizing Operation Superior kimberlite indicator mineral survey results for 1996–2000 is currently underway and is expected to be released in June of 2001.

METHODOLOGY

Bulk till samples were collected on approximately 1 km centers or as dictated by access to landing sites using a float-equipped helicopter (Bell Jet Ranger 206B). The procedure at each site was to establish, by way of hand augering, the location from which a till sample was to be collected. Once appropriate material was located, a till pit was dug to a depth that was sufficient to retrieve an unoxidized c-horizon till. Sample site locations were plotted on air photos while viewing the sites from the helicopter subsequent to sample collection. An eleven-litre pail (20–25 kg) of glacial till was collected from each sampling site and these samples were shipped to DeBeers Canada Exploration Inc. for processing. A small number of modern beach sands were also collected for analysis.

DATA DISPLAY

Mineralogical data for year 2000 samples are presented in table format with site identification, UTM coordinates (Zone 15, NAD83), mineral chemistry and indicator mineral counts. The variation in the numbers of KIMs identified in each sample is presented as bubble plots produced using ARCVIEW GIS software, digitized sample locations and analytical data.

Users will note that simplified geology of the northern Knee Lake area is presented on the bubble plots. This geology was derived from a digital version of the 1:1 000 000 bedrock map of the province (Map 79-2) and the 1:250 000 Bedrock Geology Compilation Map Series. The UTM coordinates for sample sites are derived from 1:50 000 topographic maps. Sample numbers can be derived by overlaying the mylar sample site location map (in back pocket) on the bubble plots.

KIMBERLITE INDICATOR MINERAL SURVEY—YEAR 2000

Minerals such as garnet, chromite, ilmenite and diopside in glacial sediments have been used as kimberlite indicators. Specifically, the chemistry of these grains has been used to imply their mode of occurrence in diamonds as inclusions or in kimberlites (cf. Dawson and Stephens, 1975; Gurney, 1984). All recognized kimberlite indicator minerals are chemically stable in immature glacial sediments.

Garnets have received considerable attention as kimberlite indicators and have been chemically classified according to their relevance as kimberlite indicator minerals. Calcium-depleted diamond inclusion chrome pyropes have been termed G10 (Gurney, 1984; Dawson and Stephens, 1975). They indicate a harzburgitic peridotite origin and are more closely associated with diamonds than are the garnets of lherzolitic origin, which are termed G9. Eclogitic garnets, with Na₂O concentration of greater than 0.09%, have been observed as inclusions in diamonds and also represent valuable indicator minerals.

Diamond inclusion chromites with Cr₂O₃ greater than 60% are considered to be kimberlite indicator minerals, equal in significance to G10 garnets. They are interpreted to represent sampling of diamond-bearing zones in the mantle by kimberlite magmas. High-Mg ilmenite are interpreted to reflect the reduced conditions that are necessary for the preservation of diamonds as the magma ascends through the crust. Kimberlite-hosted ilmenite generally has MgO concentrations of 4 to 15 wt % and greater than 2% Cr₂O₃. Chrome diopside with greater than 1% Cr₂O₃ has been utilized as a useful kimberlite indicator mineral (Morris et al., 1998).

Sample collection

An eleven-litre pail of glacial till was collected from each sampling site where appropriate material was encountered. These samples were shipped to DeBeers Canada Exploration Inc. at the end of the 2000 sampling program for processing.

Sample preparation and analysis

This paraphrased description of sample preparation and analysis was supplied by DeBeers Canada Exploration Inc. The eleven-litre samples were screened at 2.0 mm, with the oversize discarded except for a representative aliquot of the +2.0 to 5.6 mm fraction, which is used for pebble counts. The <2.0 mm size fraction was passed over a 0.3 mm aperture sieve and the <0.3 mm size fraction was discarded. The 0.3 mm to 2.0 mm size fraction was then concentrated by gravity separation, dried in ovens and sieved into 1.0 to 2.0 mm, 0.5 to 1.0 mm and 0.3 to 0.5 mm size fractions, which were packaged, labeled and shipped to DeBeers Canada Exploration Inc. laboratories for further treatment.

These three size fractions were individually separated using the heavy liquid bromoform (Specific Gravity: 2.86). The heavy fractions that sink through the bromoform were washed, sorted and picked for kimberlitic indicator minerals. Picked indicator minerals were then analyzed for geochemical composition by microprobe.

Preliminary interpretation of the 2000 kimberlite indicator mineral survey

The general geology and sample locations for the 2000 kimberlite indicator mineral survey in the northern half of the Knee Lake greenstone belt are provided in Figure 2a. Figure 2b (in back pocket) is a sample location mylar overlay. Guidelines for mineral classification are presented in tables 1 and 2.

The chemistry of KIMs microprobed and classified for this study is summarized in Table 3 and kimberlite indicator mineral abundances by sample site are listed in Table 4. Field boundaries for garnets and chrome spinel discriminant diagrams are from Gurney (1984; Fig. 3) and Fipke et al. (1995; Fig. 4, 5), respectively. Figure 6, a diagram depicting the parabolic relationship of Cr_2O_3 and MgO in ilmenite, is derived from the work of Haggerty (1975). Haggerty and Tompkins (1983) recognized the value of ilmenite compositions in determining the redox state of the earth's mantle and Gurney and Moore (1993) illustrated the potential for predicting diamond preservation in a kimberlite on the basis of ilmenite composition. Kimberlite indicator mineral abundances for the northern Knee Lake Belt are presented in Table 5.

Results

Total KIM abundances are plotted in Figure 7. Figures 8 through 13 are bubble plots for individual kimberlite indicator minerals throughout the 2000 survey area. These plots represent KIMs from the combined 1.0 to 2.0 mm, 0.5 to 1.0 mm and 0.3 to 0.5 mm size fractions of the sample. It is important to note that bubble plots for KIM data include all sites at which a sample was collected. To gain a true appreciation for the significance of these geographic distributions and clustering, these maps should be viewed using the mylar overlay depicting all multimedia sample locations (Fig. 2b in back pocket).

In the 2000 KIM survey samples, 5 KIM grains were recovered in the 1.0 to 2.0 mm size fraction, 86 grains were recovered in the 0.5 to 1.0 mm size fraction, and

435 grains were recovered in the 0.3 to 0.5 mm size fraction. Unlike the results from the 1998 survey no original surface remnants were observed on any of the kimberlite indicator mineral grains. This includes kelyphite and perovskite mantles on ilmenite and original surface remnants on chrome diopside grains.

Figure 7 presents total kimberlite indicator mineral abundances for the 2000 survey area. There are relatively few sites that are marked by large numbers of KIMs. These include sites 21, 32, 68, 103, 150, 166 and 175. It is important to note that sites 21, 32, 103, 150 and 175 are beach sands whereas sites 68 and 166 are till samples.

Highly elevated abundances of chrome spinel grains in the 2000 survey area (Fig. 8) are observed at site 21 where 63 grains were identified. Additionally, multiple chrome spinel grains were documented from sites 32 (12 grains), 150 (11 grains) and 68 (10 grains). Only one diamond inclusion spinel was identified in this year's survey. This grain occurs at site 35, just west of the Second Narrows (Fig. 8). Single grains of chrome diopside were identified from sites 103, 158 and 177 (Fig. 9). Titanium-chrome pyrope garnet grains are generally concentrated in samples collected in the area south of the Second Narrows. Five grains were documented from site 32 and 2 from site 103 (Fig. 10). The distribution of G9 garnets also appears to be concentrated in the area south of the Second Narrows. Fourteen G9 garnets were identified from site 32 and 5 grains were documented from site 103. Additional multigrain sites for G9 garnets are present north of the Second Narrows and along the northeastern shore of Knee Lake (Fig. 11). The distribution of G10 garnets (Fig. 12) is characterized by 8 individual sites with single G10 garnet grains. Two G10 garnets were identified at site 150 along the northeast shore of Knee Lake as well as single grains at sites 144 and 166. Magnesian ilmenite grains are concentrated at sites 32 (18 grains), 21 (12 grains), 103 (8 grains), and 6 grains at site 175 at the Second Narrows (Fig. 13).

Interpretation

Figure 14 is a schematic diagram illustrating the general trend and limits of the distribution of total KIMs identified from the survey results in 2000. Preliminary inspection would suggest a well-defined KIM dispersal trend aligned parallel to the direction of the last ice advance at approximately 235° . However, more detailed examination of the data suggests that this dispersal trend is not that well defined. The following constraints on interpretation should be noted:

1. The eastern edge of the dispersal pattern is not defined due to a lack of sampling sites;
2. The western edge of the trend coincides with a change in till composition and geomorphology marked by a transition from fluted till in the western part of the study area to non-fluted till in the east. Variations in till composition associated with fluted terrain have been observed in the Geraldton area (Thorleifson and Kristjansson, 1993) where fluted till exhibits a higher concentration of far-travelled carbonate debris that dilutes the signature of local

bedrock and results in lower KIM abundances. If this same relationship holds true in the Knee Lake area, then the dispersal trend could also be open to the west. Low concentrations of KIM in this area could reflect a change in till composition rather than the edge of a dispersal fan.

3. Samples containing the highest concentrations of KIM within the dispersal trend were collected from modern day beaches along the northeast arm of Knee Lake. Natural concentration of heavy minerals in beach sands acted to preconcentrate KIM, resulting in higher abundances in beach sands than in tills in the same area. This, plus sampling locations focused along the northeast arm of the lake, which trends parallel to the last ice advance, have exaggerated the apparent trend of KIM distribution in the same direction.

CONCLUSIONS

1. The absence of original surface remnants on the KIM grains suggests some distance of transport and therefore a KIM source northeast of the 2000 survey area.
2. The 2000 kimberlite indicator mineral survey has delineated a northeast-trending dispersal pattern that is parallel to the last ice advance at approximately 235° azimuth. This trend represents a northern extension of the trend identified in the 1999 open file report (Fedikow et al., 2000) for the southern Knee Lake area.
3. The dispersal trend identified in the northern portion of the Knee Lake Belt in 2000 is based upon a significantly higher number of KIMs than the dispersion trend identified in the southern portion of the belt. However, five of the seven sites with the highest KIM abundances are beach sands collected along the northeast arm of Knee Lake that trends parallel to ice flow. This may have exaggerated the apparent trend of KIM distribution in this direction.
4. The eastern boundary of the trend is approximate due to a lack of samples in this area.
5. The western edge of the trend coincides with a change in till composition and geomorphology marked by a transition from fluted till in the western part of the study area to non-fluted till in the east. The heavily fluted, drumlinized terrain to the northwest is characterized by very few KIMs and low concentrations of KIM in this area could reflect a change in till composition rather than the western edge of the dispersal trend. Non-drumlinized till, on the basis of significantly elevated numbers of kimberlite indicator minerals, represents the preferred sampling medium for diamond exploration in this area.

ACKNOWLEDGMENTS

Dave Tomlin and Jamie Gould, Provincial Helicopters Limited (Lac du Bonnet), are acknowledged for their

considerable skills in safely accessing sample sites for the 2000 season. Important logistical support was provided by the staff of the Knee Lake Lodge, specifically Bill Page, and was greatly appreciated. Chris Bater, Ryan Oger and Zoe Kepron are thanked for their enthusiastic support during the 2000 sampling season. Harvey Thorleifson, Terrain Sciences, Geological Survey of Canada is thanked for providing guidance with kimberlite mineral identification. Neill Brandson is thanked for logistical support during the field component of the project. Acknowledgments also go to Doug Berk, Rick Unruh, Gerry Benger, Vio Varga, Zoe Kepron and Harriet Beardy for careful sample preparation and Don Snuggs for his analytical expertise and care with pH and conductivity measurements. We are grateful to Tim Corkery and Ric Syme for discussions relating to geological observations in the sampling areas. The interpretation of the KIM patterns in this study were significantly improved by Christine Kaszycki. Ifti Hosain provided valuable insights into the geophysical surveys conducted in the greenstone belts. Al Bailes and Ric Syme are thanked for their constructive criticism and technical review of the manuscript. Kelly Proutt is thanked for typing the manuscript and general assistance with construction of the report. Monique Lavergne edited the final version of this report and Craig Steffano was responsible for desktop publishing.
