INTRODUCTION

In 1996, the Manitoba Geological Services Branch (now the Manitoba Geological Survey) embarked upon a six-year program of helicopter- and fixed wing-assisted multimedia geochemical and mineralogical sampling. The program, called Operation Superior, was designed to assist in the definition of exploration targets and the assessment of mineral resource potential in the greenstone belts of the northern Superior Province using current and innovative technologies. Preliminary results for the areas surveyed in 1996, 1997, 1998, 1999 and 2000 were released in Fedikow and Nielsen (1997) and Fedikow et al. (1997a, b, 1998, 1999, 2000, 2001, 2002).

A unique opportunity to assess the diamond potential in the northern Superior Province of Manitoba was made possible with the cooperation of De Beers Canada Exploration Inc. Eleven-litre pails of till collected at each sampling site were concentrated, mineralogically picked and analyzed by electron microprobe at De Beers laboratories to provide mineral chemistry for classification purposes. Sample locations were withheld from De Beers until release of the open file reports to ensure security and equal opportunity for follow-up by all interested parties in the exploration community. This approach permitted diamond potential to be assessed throughout the 1996-2001 Operation Superior survey areas, an undertaking that under normal circumstances would have been too costly for the Manitoba Geological Survey.

This open file departs from the previous Operation Superior releases in that the results of kimberlite indicator-mineral (KIM) surveys are normally reported along with rock, a- and b-horizon soil, till and vegetation geochemical data. This report presents the results of KIM survey data acquired during the six-year term of Operation Superior (Fig. 1).

QUATERNARY GEOLOGY OF THE OPERATION SUPERIOR KIMBERLITE INDICATOR MINERAL SURVEY AREA

Early glaciation

The northern Superior Province of Manitoba has been glaciated many times during the Quaternary, but evidence for all but the last glaciation is scant. The presence of erratics from central Keewatin, Hudson Bay and eastern Hudson Bay, as well as westerly, southwesterly and southeasterly striae, testify to a long and complex ice-flow history. However, depositional evidence for the early events indicated by southeasterly and westerly striae has not been forthcoming outside the Hudson Bay Lowland (the northeastern limit of esker development). Although these early ice-flow events are of some interest, they have little relevance to overburden geochemical and mineralogical exploration in most of the northern Superior Province.

Ice-flow history

The last ice advance to affect the northern Superior Province deposited a thin and almost continuous till sheet

over much of the area. The southwesterly flowing ice, which originated in Hudson Bay to the north and east of the area, formed a large lobe centred on the northern Superior Province (Fig. 2). The ice lobe was bounded by the Limestone Moraine to the north, the Settee and The Pas moraines to the west and southwest, and the George Island Moraine to the south (Klassen, 1986; Nielsen and Thorleifson, 1996). Striae, drumlins, eskers and other ice-flow directional indicators are orientated toward the southwest (230-250°) along the longitudinal axis of the lobe, whereas toward the flanks of the lobe, the ice-flow directions fan out (Fig. 3). Along the northwestern flank of the lobe, such as in the Stephen's Lake-Split Lake area, the ice flow was toward 285°. Similarly, along the eastern flank of the lobe, such as in the Little Stull Lake area, ice flow was toward 170°.

Ameliorating climate conditions at the end of the Pleistocene resulted in the gradual northeast retreat of the ice margin, as indicated by a series of near-parallel moraines, including the Hargrave-Hudwin-Sachigo and Burntwood-Sipiwick-Bigstone moraine systems (Klassen, 1986). Readjustment of the ice profile and ice-marginal configuration during glacial retreat resulted in small changes in the ice-flow trajectory, as indicated, in places, by crossing striae and minor, local ice-flow variations.

Till sheet

The last ice flow deposited an almost continuous sheet of calcareous till that was derived, in large part, from Paleozoic carbonate bedrock and previously deposited calcareous (glacial, various nonglacial and marine) sediments in Hudson Bay and adjacent Hudson Bay Lowland. The till sheet was deposited both as a veneer and as drumlins and drumlinoid ridges across the area.

The till veneer is generally only a few metres thick and more discontinuous than the drumlinized till. In places, it is interrupted by extensive bedrock outcroppings. The till veneer is common in the distal or more peripheral parts of the ice lobe where the carbonate content (indicative of Hudson Bay Lowland provenance) is the lowest in the region. The low carbonate content in the peripheral areas (Fig. 4) is believed to be due to dilution by local Precambrian rock types entrained during glacial transport across the intervening terrain from the Hudson Bay Lowland (Matile and Thorleifson, 1997).

The drumlinized till is most common in the proximal and central part of the ice lobe. The carbonate content is high, but not unlike that of the till veneer in the same region. The drumlinized till and till veneer are generally not compositionally distinct and cannot be differentiated using carbonate content. The drumlins and drumlinoid ridges typically attain heights of 5-10 m and lengths in excess of a kilometre. The drumlins and drumlinoid ridges throughout the region are not exclusively composed of the same light buff, calcareous and silty till. In places, such as in the area east of Oxford House, they are composed of glaciofluvial sand and gravel (Fedikow et al., 2000). As well, at several sites between Knee Lake and Stupart Lake, they are composed of Sky Pilot till, a

reddish silty till that is widely distributed across the Hudson Bay Lowland (Nielsen et al., 1986; Fedikow et al., 2002). The variable internal composition, the long linear form and the internal structure all suggest that the drumlinoid shape is an erosional form, not related to the composition or provenance of the enclosing material (T. Brennan and H. Thorleifson, pers. comm., 2000).

Glaciolacustrine sediments

After deglaciation, glacial Lake Agassiz inundated the area. The inundation resulted in the deposition of an extensive blanket of fine-textured glaciolacustrine sediment over the previously deposited till sheet. Low-lying areas were filled with silt and clay deposits that pinch out along the flanks of the surrounding hills and prominent topographic highs, such as bedrock hills and esker ridges. Drumlins and drumlinoid ridges generally remained uncovered. The widespread deposits of glaciolacustrine silt and clay are the single largest detriment to till sampling from hand-dug pits. However, where the glaciolacustrine sediments can be penetrated in hand-dug pits (<1m), relatively unweathered till, which is desirable for geochemical analysis, may be obtained. On the other hand, till collected from topographic highs without a covering of glaciolacustrine silt and clay has generally been exposed to postglacial pedogenic processes. Near-surface weathering (oxidation and leaching) of the till is common at such sites.

The tops of prominent topographic highs were eroded during the general regression of glacial Lake Agassiz. When the water level dropped, hilltops became exposed to wave base, and boulder lags and washed bedrock surfaces formed as the till was eroded.

SURVEY METHODOLOGY

Bulk till samples were collected on approximately 1 km centres or as dictated by access to landing sites using a float-equipped helicopter (Bell Jet Ranger 206B). The procedure at each site was to establish, by way of hand augering, the location from which a till sample could be collected. Once appropriate material was located, a till pit was dug to a depth that was sufficient to retrieve a relatively unoxidized c-horizon till sample. Sample sites were plotted on airphotos while viewing the sites from the helicopter after sample collection.

DATA DISPLAY

Mineralogical data for samples collected between 1996 and 2001 are presented in table format with site identification, UTM coordinates (Zone 15, NAD83), mineral chemistry and indicator mineral counts. The variation in the numbers of KIMs identified in each sample is presented as bubble plots produced using ARCVIEW GIS software, digitized sample locations and analytical data.

Users will note that the simplified geology of the northern Superior Province is presented on the bubble plots. This geology was derived from a digital version of

the 1:1 000 000 bedrock map of the province (Map 79-2) and the 1:250 000 Bedrock Geology Compilation Map Series. The UTM coordinates for sample sites are derived from 1:50 000 topographic maps.

KIMBERLITE INDICATOR MINERAL SURVEY, 1996–2001

Minerals such as garnet, chromite, ilmenite and diopside in glacial sediments have been used as kimberlite indicators. Specifically, the chemistry of these grains has been used to imply their mode of occurrence in diamonds as inclusions or in kimberlites (cf. Dawson and Stephens, 1975; Gurney, 1984). All recognized kimberlite indicator minerals are chemically stable in immature glacial sediments.

Garnets have received considerable attention as kimberlite indicators and have been chemically classified according to their relevance as kimberlite indicator minerals. Calcium-depleted diamond-inclusion chrome pyrope garnets have been termed G10 (Gurney, 1984; Dawson and Stephens, 1975). They indicate a harzburgitic peridotite origin and are more closely associated with diamonds than are the garnets of lherzolitic origin, which are termed G9. Eclogitic garnets, with an Na₂O concentration of greater than 0.09%, have been observed as inclusions in diamonds and are also therefore valuable indicator minerals.

Diamond-inclusion chromites with Cr₂O₃ greater than 60% are considered to be kimberlite indicator minerals, equal in significance to G10 garnets. They are interpreted to represent sampling of diamond-bearing zones in the mantle by kimberlite magmas. High-Mg ilmenites are interpreted to reflect the reduced conditions that are necessary for the preservation of diamonds as the magma ascends through the crust. Kimberlite-hosted ilmenite generally has MgO concentrations of 4 to 15 wt % and greater than 2% Cr₂O₃. Chrome diopside with greater than 1% Cr₂O₃ has proven to be a useful kimberlite indicator mineral (Morris et al., 1998).

Sample collection

An eleven-litre pail (20-25 kg) of glacial till was collected from each sampling site where appropriate material was encountered. These samples were shipped to De Beers Canada Exploration Inc. at the end of each year's sampling program for processing. A small number of modern beach sands were also collected for analysis.

Sample preparation and analysis

The following paraphrased description of sample preparation and analysis was supplied by De Beers Canada Exploration Inc.

The eleven-litre samples were screened at 2.0 mm, with the oversize discarded except for a representative aliquot of the +2.0 to 5.6 mm fraction, which is used for pebble counts. The <2.0 mm size fraction was passed over a 0.3 mm aperture sieve and the <0.3 mm size fraction was discarded. The 0.3 mm to 2.0 mm size

fraction was then concentrated by gravity separation, dried in ovens and sieved into 1.0 to 2.0 mm, 0.5 to 1.0 mm and 0.3 to 0.5 mm size fractions, which were packaged, labelled and shipped to De Beers Canada Exploration Inc. laboratories for further treatment.

The three size fractions were individually separated using the heavy liquid bromoform (specific gravity 2.86). The heavy minerals that sank through the bromoform were washed, sorted and picked for kimberlitic indicator minerals. Picked indicator minerals were then analyzed for geochemical composition by electron microprobe.

Preliminary interpretation of the 1996-2001 kimberlite indicator mineral surveys

The locations of KIM surveys for each year of Operation Superior are given in Figure 1. Figure 2 portrays drumlin and esker orientation in the northern Superior Province. Field boundaries for garnets and chrome spinel discriminant diagrams are from Gurney (1984; Fig. 5) and Fipke et al. (1995; Fig. 6, 7), respectively. Figure 8, a diagram depicting the parabolic relationship between Cr_2O_3 and MgO in ilmenite, is derived from the work of Haggerty (1975). (Please note that the diagrams for Figure 5 through 8 do not include 2001 data.) Haggerty and Tompkins (1983) recognized the value of ilmenite compositions in determining the redox state of the earth's mantle, and Gurney and Moore (1993) illustrated the potential for predicting diamond preservation in a kimberlite on the basis of ilmenite composition. Figures 9 through 14 are bubble plots that give the abundances of KIMs in an eleven-litre pail from each sampling site. Figure 15 presents total KIMs for the survey area.

Guidelines for mineral identification (Thorleifson et al., 1994) are presented in tables 1 and 2. Table 3 summarizes KIM abundances for the Operation Superior survey area. It also includes a subset of KIM data for the Echimamish River (1996) and the northern (2000) and southern (1999) portions of the Knee Lake greenstone belt.

The chemistry of KIMs analyzed by microprobe and classified for this survey is presented in Appendix 1, and KIM abundances by sample site are listed in Appendix 2.

RESULTS

Figures 9 through 14 are bubble plots for individual kimberlite indicator minerals throughout the 1996-2001 survey area, whereas Figure 15 summarizes total KIM abundances. These plots represent KIMs from the combined 1.0 to 2.0 mm, 0.5 to 1.0 mm and 0.3 to 0.5 mm size fractions of the sample.

A total of 1253 KIMs were recovered from 1243 samples during Operation Superior. The highest concentrations of KIMs were found in the Knee Lake belt and at a site along the Echimamish River belt southwest of Lawford Lake. Comparatively, the Echimamish River site has significantly fewer KIMs than the Knee Lake belt. A total of 37 KIM grains were recovered from 10 samples collected at the Echimamish River site, as compared to 835 KIM grains in the Knee Lake belt.

The presence of alteration rims or original surface textures on the surface of KIMs, including kelyphite and perovskite mantles on ilmenite and original surface remnants on chrome diopside grains, can be used to infer transport distances. A total of five Cr-diopside grains with original surface remnants were observed in the 1998 KIM survey. Three of these grains occur in the Knife Lake belt (sites 95, 110 and 118) and two in the Echimamish River belt (sites 39 and 192). In addition, two Cr-diopside and one Mg-ilmenite grains from the 2001 survey to the east of the north end of Knee Lake had remnant perovskite mantles. One Cr-diopside grain was from site 11 east of the south end of Swampy Lake and the other from site 276 east of Swampy Lake. Original surface remnants were also observed on one Mg-ilmenite grain from site 21 just east of the northern end of Knee Lake. These features were not observed on any other KIM grains during Operation Superior. The absence of surface remnants on KIM grains from glaciofluvial or modern beach sands is not unexpected. These sample types are derived from till and have been extensively or, in the case of modern beach sands, continually reworked in an active erosional environment.

The distribution and abundances of individual KIMs throughout the Operation Superior project area are discussed below. The specifics for KIM abundances in the Knee Lake and Echimamish River belt are discussed separately and compared to the total KIM abundances in the Operation Superior survey area in Table 3.

Cr-spinel (Figure 9)

A total of 484 Cr-spinel grains were documented during the 1996-2001 KIM survey. Cr-spinel is the second most abundant KIM identified. The majority of Cr-spinel grains are concentrated in samples from the Knee Lake belt, primarily in the northern half of the belt. This includes one of two diamond-inclusion spinels documented during Operation Superior. The second spinel occurs southeast of Max Lake in a position that is down-ice from the KIM trend identified in the Knee Lake belt. A single site with seven Cr-spinel grains occurs east of Beaverhill Lake.

Cr-diopside (Figure 10)

Multiple sites with a single Cr-diopside grain occur throughout the Operation Superior survey area. A site with two Cr-diopside grains occurs south of the Colen Lakes, the Echimamish River site had one grain, and six sites in the Knee Lake belt had one grain each. Two grains from the 2001 survey to the east of the north end of Knee Lake had remnant perovskite mantles. One of the grains was from site 11 east of the south end of Swampy Lake (0.3–0.5 mm; remnants of the original surface) and the other from site 276 east of Swampy Lake (0.3–0.5 mm; remnants of the original surface). Chrome diopside grains are absent from the drumlinized terrain in the northwest portion of the Knee Lake belt but both grains from the 2001 survey east of Knee Lake were from drumlinized till. Twenty-eight Cr-diopside grains were recovered from the 1996-2001 survey.

Ti-Cr pyrope (Figure 11)

Low abundances of Ti-Cr pyrope grains are observed throughout the Operation Superior survey area. Sixty grains were identified in samples collected during Operation Superior, with over half of these occurring in the Knee Lake belt. The majority occur in nondrumlinized terrain in the northeast portion of the belt. However, Ti-Cr pyrope grains also occur in drumlinized till west of Knee Lake. The distribution of the Ti-Cr pyrope grains in the Knee Lake belt approximates the last ice advance at 235°, although this result is skewed by the areal extent and down-ice orientation of the belt.

G9 garnets (Figure 12)

A total of 163 G9 garnets were recovered from the Operation Superior survey. The majority of these grains occur in nondrumlinized terrain in the northern portion of the Knee Lake belt although they occur in drumlinized till both to the east and west of Knee Lake. A total of six grains was found in samples from the Echimamish River site. Elsewhere, the grains are distributed throughout the area of the greenstone belts without obvious clusters.

G10 garnets (Figure 13)

Most G10 garnets were identified from samples collected in nondrumlinized terrain in the northern portion of the Knee Lake belt. Two G10 garnets occur in samples from drumlinized terrain at Knee Lake. A chrome pyrope from a site northeast of Knee Lake plots in the G10 field (Gurney, 1984) in Figure 3 however, the grain straddles the G10/G9 boundary. This same grain would not be considered a G10 if it were classified using the equations of Thorleifson et al., (1994). Only seven G10 garnet grains were identified outside of the Knee Lake area and these are scattered across the Operation Superior survey area. There is only one site, a beach sand sample from northern Knee Lake, that contains more than one G10 garnet grain. A single G10 garnet grain occurs east of the dispersion trend identified at the Echimamish River site. Twenty-nine G10 garnets were documented during Operation Superior.

Mg-ilmenite (Figure 14)

Magnesian ilmenite grains were the most abundant KIM identified during Operation Superior (n=472). These KIMs are concentrated in samples from the Knee Lake belt, including those from both drumlinized and nondrumlinized terrain. Original surface remnants were observed on one ilmenite grain (1.0–2.0 mm; perovskite mantle) from a site just east of the northern end of Knee Lake. A second cluster of 22 grains occurs in the Echimamish River area. Magnesian ilmenite occurs primarily as one to two grains at most sites throughout the Operation Superior survey area. An eight-grain cluster from five sample sites occurs west of Kistigan Lake.

Total kimberlite indicator minerals (Figure 15)

The distribution of total KIMs in the Operation Superior survey area shows that the highest concentration of KIMs occurs in the Knee Lake greenstone belt. A

total of 1253 KIM grains were identified during Operation Superior, with the majority of these occurring in the Knee Lake belt. The Echimamish River site is marked by 37 KIMs and is the only other KIM dispersion trend present in the 1996–2001 survey data. Total KIMs in the Knee Lake belt and at the Echimamish River site define apparent KIM trends that parallel the last ice advance at approximately 235°. Constraints on this observation are discussed in the next section.

DISCUSSION

Kimberlite indicator minerals in the Knee Lake greenstone belt

There are relatively few sites in the Operation Superior survey area that are marked by large numbers of KIMs. Figures 9 through 15 and Table 3 indicate significantly elevated KIM abundances in samples collected from the Knee Lake greenstone belt and from one site in the Echimamish River belt that define a trend parallel to the last ice advance. High KIM abundances in samples from the Knee Lake belt include sites 21, 32, 68, 103, 150, 166 and 175 in the northern half of the belt. It is important to note that sites 21, 32, 103, 150 and 175 are beach sands, whereas sites 68 and 166 are till samples. In the southern half of the belt, site 104 (till) contains 30 KIM grains. The sample at site 104 was collected on strongly foliated gabbro bedrock. The eight sites mentioned above contribute significantly to the KIM trend oriented at 235°.

Preliminary inspection indicate a KIM dispersal train aligned parallel to the direction of the last ice advance at approximately 235°. Some constraints on the interpretation and significance of this trend should be noted:

- 1) Kimberlite indicator mineral surveys, like the multi-media geochemical surveys, were confined to the mapped boundaries of greenstone belts and not undertaken in intervening areas of intrusive rocks. This approach significantly restricted the ability to define KIM dispersion trains in most areas. As a result, the eastern edge of the Knee Lake dispersal pattern is not well defined due to a lack of sampling sites except possibly in the north. Sampling in the Fish Lake–Knee Lake area in 2001 found relatively few kimberlite indicator minerals compared to the surveys in the Knee Lake area carried out in the two previous years suggesting the Knee Lake dispersion train is not "open" to the east.

- 2) The western edge of the trend in the northern half of the belt coincides with a change in till thickness and geomorphology, specifically a transition from drumlinized till in the western part of the study area to nondrumlinized till in the east. The apparent control of KIM abundances in drumlinized versus nondrumlinized till was discussed in Fedikow et al. (1999) for the southern half of this belt. Variations in till composition associated with drumlinized terrain have also been observed in the Geraldton area of Ontario (Thorleifson and Kristjansson, 1993), where drumlinized till exhibits a higher concentration of far travelled carbonate debris that dilutes the signature of local bedrock and results in lower KIM abundances. If this

same relationship holds true in the Knee Lake area, the dispersal trend could also be open to the west. Low concentrations of KIMs in this area could simply reflect a change in till composition rather than the edge of a dispersal fan. However, the carbonate content of the drumlinized and nondrumlinized till samples is similar suggesting a similar provenance, a conclusion that is supported by the colour, texture and chemistry of the tills in the Knee Lake area. Also, drumlinized areas both east and west of Knee Lake contain some, albeit lesser concentrations of KIMs than the nondrumlinized till.

3) Many of the samples containing the highest concentrations of KIMs within the dispersal trend were collected from modern beaches along the northeast arm of Knee Lake. Natural concentration of heavy minerals in beach sands acts to preconcentrate KIMs, resulting in higher abundances in beach sands than in till samples from the same area (Table 3). The orientation and areal extent of the greenstone belt served to focus sampling locations along the northeast arm of the lake. The northern portion of the belt trends parallel to the last ice advance and has therefore exaggerated the apparent trend of KIM distribution in the same direction.

It should be noted that the 'beach' sands from Knee Lake are not stream-sediment samples and are deposited in a distinctive manner. Knee Lake occupies a basin and any coarse material, such as sand, that is brought into the lake is deposited where the river enters the lake. Sand is not transported by longshore drift around the shores of the lake and out via the Hayes River. The beaches sampled in the northern half of Knee Lake are 'pocket beaches' that have developed locally from the erosion of till at that site. When tills erode to produce sand, the material is carried out into deep water along the shore of the lake. If there was longshore transport, there would have to be sandy beaches along the entire south-east shore, a feature that is not observed at Knee Lake. The observation that some beaches on Knee Lake do not contain any KIMs supports the contention that KIMs in beach sands at Knee Lake are likely derived from nearby till.

Beach-sand samples generally have higher percentages of heavy minerals than the till from which they were derived. This may result in a disproportionately higher number of indicator minerals for beach-sand samples compared to till samples from the same area.

Kimberlite indicator minerals in the Echimamish River greenstone belt

A moderately well defined KIM dispersal trend has been documented in an area designated as the Echimamish River site. This trend is associated with a serpentinized ultramafic unit that was observed in outcrop and in one till pit at this site. The dispersion trend is characterized by twenty-three Mg-ilmenite grains, five Cr-spinel grains, five G9 garnets, two Ti-Cr pyrope garnets and one Cr-diopside grain. A single G10 garnet occurs in a sample collected east of this dispersal trend. The trend parallels the last ice advance at approximately 235° but is not well defined due to the limited sampling east and west along the Echimamish River greenstone

belt. There are no sample sites north of the belt and it is therefore uncertain whether the dispersal trend reflects the ultramafic unit that outcrops at the northern edge of the belt.

CONCLUSIONS

1) Kimberlite indicator mineral (KIM) abundances are generally low in the greenstone belts sampled during Operation Superior. Nevertheless, two distinctive areas of elevated KIM abundances and dispersion trends occur in the Knee Lake and Echimamish River greenstone belts.

2) Two southwest-trending dispersal patterns parallel to the last ice advance (at approximately 235°), have been identified in the Knee Lake greenstone belt and from one site in the Echimamish River belt. The Knee Lake trend represents a northern extension of the trend identified in the 1999 survey (Fedikow et al., 2000) for the southern Knee Lake area.

3) The dispersal trend identified in the northern portion of the Knee Lake belt in 2000 is based upon a significantly higher number of KIMs than the one identified previously in the southern portion of the belt. However, five of the seven sites with the highest KIM abundances are beach sands collected along the northeast arm of Knee Lake, which itself trends parallel to ice flow. This may have exaggerated the apparent trend of KIM distribution in this direction. A till sample collected over strongly foliated gabbro bedrock in the southern portion of the Knee Lake belt contained 30 KIMs.

4) The eastern boundary of the Knee Lake KIM trend is defined in the north by sampling in 2001 which clearly indicates the dispersion train is not open to the east. The western edge of the Knee Lake trend coincides with a change in geomorphology, specifically a transition from drumlinized till in the western part of the study area to nondrumlinized till in the east. The heavily drumlinized terrain to the northwest is characterized by few KIMs, which could reflect a difference in till thickness rather than the western edge of the dispersal trend. Nondrumlinized (thin) till, on the basis of significantly elevated numbers of KIMs, represents the preferred sampling medium for diamond exploration in this area.

5) The KIM trend in the Echimamish River belt is based on a smaller number of KIMs and is open to the northeast and southwest. Like the Knee Lake trend, it also parallels the last ice advance at 235°. A line of till samples extending west from the west end of Lawford Lake and analyzed for KIM contents could help to determine whether 1) this trend is related to the ultramafic intrusion identified during sampling or 2) the source region occurs elsewhere.

6) The absence of original surface remnants on the majority of KIM grains suggests some distance of glacial transport and therefore a KIM source in the north-eastern part of Knee Lake and possibly north of the Echimamish River greenstone belt.

ACKNOWLEDGMENTS

John Gibson and the crews of Provincial Helicopters

Limited (Lac du Bonnet) are acknowledged for their considerable skills in safely accessing sample sites for the 1996-2001 surveys. Important logistical support was provided by Darrell McKay and staff at Manitoba Hydro (Jenpeg) and by Bill Page (Director of Maintenance) at Knee Lake Lodge, and is gratefully acknowledged. Numerous summer students from Manitoba universities made significant contributions to Operation Superior and are thanked for their efforts under difficult circumstances. Ron DiLabio and Harvey Thorleifson (Terrain Sciences Division, Geological Survey of Canada) are thanked for providing software and guidance with kimberlite indicator mineral identification. Neill Brandson is thanked for his consistent logistical support during the field component of the project. Acknowledgments also go to Doug Berk, Rick Unruh, Gerry Bengier, Vio Varga and Don Snuggs for careful sample preparation. We are grateful to Tim Corkery, Ric Syme and George Gale for discussions relating to geological and mineral deposits observations in the northern Superior Province. Ifti Hosain provided valuable insights into the geophysical surveys conducted in the greenstone belts. Al Bailes, Ric Syme and Christine Kaszycki are thanked for constructive criticism and technical reviews over the years. Kelly Proutt is thanked for help with manuscript preparation. Monique Lavergne edited the final version of this report and Craig Steffano was responsible for desktop publishing.
